

While pulling an all-nighter at the campus gaming room, your computer lab's vintage arcade cabinet suffered a massive power surge. Lightning struck the transformer, a spark jumped the coin slot, and **Alex** (our student protagonist) got digitized and sucked straight into the cabinet's corrupt 8-bit motherboard.

The system has been seized by **The Glitch Master** (a rogue boss AI), who has locked down every sector of the game ROM. The only way to reboot the machine and extract Alex back into the physical world is to recover all the missing memory blocks by completing sector tasks.

Alex - The Trapped Player

The Glitch Master - The Villian

Byte - Friend of Alex

Origin: The arcade machine was running a half-finished, abandoned retro game. When the lightning/power surge struck, the unfinished boss code merged with the cabinet's corrupted firmware, creating an autonomous entity called "**The Glitch King**" (or **Master Glitch**).

Personality & Goal: Glitch loves its new reality and wants to keep the arcade cabinet running forever so it stays alive. If Alex triggers a system reboot, the power cuts, the corrupted memory flushes, and Glitch is wiped from existence.

Why it fights back: To prevent Alex from rebooting the cabinet, Glitch locked down the system by scrambling sectors, corrupting data tables, encrypting files, and locking sub-routines (the CTF challenges).

Glitch added multiple locks to reboot and saved all keys to different locations. And to keep them remembering it gave each a question and hint. Get all of these to reboot this arcade and get the glitch out of arcade.
